ABSTRACT
Research has shown that implementation of corporate social responsibility (CSR) practice represents a considerable challenge for small and medium-sized enterprises (SMEs). This research conceptualises the dimensions and contingencies of CSR in SME supply chains. Drawing on institutional theory and stakeholder theory, we investigated the degree of importance and implementation of CSR practices in SMEs. A large-scale questionnaire survey with SMEs in manufacturing sectors and panel discussions were conducted in South Korea. The findings indicate that SMEs tend to focus on explicit CSR practices that can be easily identified by their customers. Consistent with this, stakeholder and institutional pressures were valid in the performance of CSR practices, but largely biased to customers, government, and regulatory pressures. Based on institutional theory and stakeholder theory as overarching theoretical lenses, this research contributes to a fuller understanding of the dimensions of CSR practices in the supply chains from an SME perspective. Introduction

IN LINE WITH THE INCREASINGLY SHARED CONSENSUS THAT ORGANISATIONS SHOULD IMPLEMENT CORPORATE SOCIAL RESPONSIBILITY (CSR) practices, the form and concept of CSR has become prevalent in business research which led to various conceptualisations by scholars. To date, developing a widely accepted conceptualisation of CSR is highly contested in the literature (McWilliams et al., 2006; Welford et al., 2007; Heikkurinen & Ketola, 2012). Given the complexity of the CSR concept, it is viewed mainly from four perspectives: as a social obligation, as a stakeholder obligation, as an ethics-driven process, and as a strategic managerial process (Maignan & Ferrell, 2004;
Oberseder et al., 2013). Within these CSR perspectives, CSR research and practice lies on a paradox between a notion of voluntary basis or behaviour of social concerns in companies’ operations (Vilanova et al., 2008) and an opposing notion of social responsibilities that is typically mandated by law (Campbell et al., 2012). In any case, the public’s awareness of CSR has been increasing, which has led firms to implement CSR practices across their supply chains.

The integration of CSR into supply chains has drawn much attention both from practitioners and researchers with the current emphasis on the triple bottom line of economic, environmental, and social concerns of business operations. However, sustainable supply chain management (SSCM) research is largely biased towards economic and environmental aspects (Hall & Matos, 2010), which highlights the importance of CSR research focusing on both environmental and social impacts of the business beyond economic concerns. Research on CSR practices in supply chain management (SCM) is rather limited but it is becoming a field of increasing interest, with research particularly concentrating on the CSR practices and activities of large companies in their supply chains. Within CSR in SCM research, the implementation of environmental and social standards along the supply chains (Seuring & Muller, 2008) and the risks and challenges related to implementing and complying with these environmental and social standards (Lim & Philips, 2008) have been studied. Implementing CSR practices in the supply chain can be challenging and yet, despite the increasing awareness of implementing CSR in supply chains, many firms, specifically small and medium-sized enterprises (SMEs), struggle to see the real value of CSR practices in terms of competitive advantages across the supply chains (Welford & Frost, 2006).

Because the distribution of CSR complements the supply chains by linking buyers and suppliers, the focus should integrate responsibilities of and for those parties into a company’s role to implement socially responsible business. In addition, the scope is limited to large companies and public authorities, neglecting SMEs in the sustainability debates (Achabou et al., 2015; Johnson, 2015). With CSR becoming increasingly critical to today’s organisations, be they small or large, there is a need to fully understand the CSR debates of SMEs as they tend to struggle to implement CSR practices. Indeed, SMEs are in a weak position in supply chains and possess fewer resources, and have a smaller scope of operations and lower visibility compared to large firms, which often leads to their passive reactions to CSR practices and implementation. Given the research gaps, this research aims to conceptualise the dimensions of CSR in supply chains and investigate the degree of implementation of these CSR practices from an SME perspective. It also explores the drivers of CSR which initiate and motivate firms to adopt CSR based on institutional theory (Kim et al., 2013) and stakeholder theory (Park & Ghauri, 2015) as overarching theoretical lenses.

We believe that having a multidisciplinary perspective contributes to the advancement of research on CSR in supply chains. Under this notion, we provide a consolidated dimension to investigate CSR and SCM relationships and advance the theoretical understanding of CSR in SME supply chains. The objectives of this paper are three-fold. The first is to conceptualise the dimensions of CSR in supply chains, highlighting which CSR dimensions are prioritised in practice. The second is to demonstrate to what degree SMEs implement CSR practices. The third is to explore the drivers of SMEs’ CSR practices based on institutional theory and stakeholder theory. We employ the empirical findings of SME supply chains to illustrate this theoretical development. To address the objectives, we investigated South Korean SMEs in manufacturing industries who are involved in global supply chains. We conducted a large-scale questionnaire with manufacturing SMEs in the Gyeongbuk province in South Korea.

The remainder of this paper is structured as follows. In the next section, we review the extant research that shed light on the dimensions and drivers of CSR in supply chains. Then, the methodological approach of the empirical study is explained and after which the findings are presented and discussed. Finally, conclusions are drawn, including theoretical and practical implications for SME management with limitations of the study.

Literature Review

CSR in SME Supply Chains

For this paper, we take the view of CSR as a concept whereby companies go beyond and extend to the grounding CSR on a voluntary basis and integrate the greater notion of socially binding responsibilities in their business...
operations and in their interface with their stakeholders. Thus, our study adheres to the definition by McWilliams and Siegel (2001, p. 117) where they define CSR as ‘actions that appear to further some social good, beyond the interests of the firm and that which is required by law’. This interpretation of CSR suggests the potential dimensions of CSR practices of business operations where CSR is firmly connected to institutions of stakeholder or government involvement (Heikkurinen & Ketola, 2012; Brunton et al., 2015). When engaging with stakeholders, CSR can be viewed as an imperative organisational task for firms to address ethical, social, environmental, and economic demands (Park & Ghauri, 2015).

Extending the notion of CSR to not only being socially responsible within the organisation internally, CSR encompasses the idea of a company being responsible socially and environmentally throughout its supply chain (Pedersen & Andersen, 2006). Research on how to integrate CSR into SCM is rather limited but it is becoming a field of increasing interest, with research particularly concentrating on the CSR practices and activities of large corporations in their supply chains. Within CSR in supply chains, the implementation of environmental and social standards along the supply chains (Seuring & Muller, 2008) and the risks and challenges related to implementing and complying with these environmental and social standards (Lim & Philips, 2008) have been researched.

Implementing CSR practices in supply chains can be challenging and yet, despite the increasing awareness, many firms struggle to see the real value of CSR practices in terms of business profits and performance. In particular, traditional concepts of CSR cannot fully capture the social responsibilities of supply chains beyond a company. Since the distribution of CSR complements the supply chains by linking buyers and suppliers, it is necessary to take buyers and suppliers into account when implementing sustainability within supply chains. For this reason, Carbone et al. (2012) distinguished supply-chain-level responsibilities from business-level responsibilities while incorporating both social and environmental dimensions for both levels. However, there are just a few studies which consider the uniqueness of supply-chain-level responsibilities, thus conceptualisation of these aspects is not common in the literature.

With respect to the organisational size in CSR-related activities and practices, the literature tends to focus on large corporations such as multinational enterprises (MNEs) in developed countries (Jackson et al., 2008) and to neglect SMEs in the current sustainability and sustainable development debates (Bos-Brouwers, 2010; Cassells & Lewis, 2011; Lee et al., 2016.). There is a clear knowledge gap in the link between CSR-SMEs (Perez-Sanchez et al., 2003; Russo & Perrini, 2010) although SMEs make up over 90% of the global population of corporations and offer more than half of employment in both developed and developing economies (Udayasankar, 2008; Jamali et al., 2009). Consequently, SMEs produce major contributions in social and economic-related activities (Udayasankar, 2008). Given their importance, this gap needs to be addressed by focusing on CSR, putting emphasis specifically on SMEs. Towards a more holistic approach in CSR, there is a need for more research into CSR in SCM specifically from an SME perspective (Pedersen, 2009; Ayuso et al., 2013). Typically, SMEs often seem to possess intrinsic differences when compared with large corporations. These differences come in the form of legal structures, policies, sector, strategic orientation towards profit, and institutional forms (Perrini, 2006).

Within the SME environment, extant CSR theories and instruments suited for MNEs may not be applicable for SMEs (Bos-Brouwers, 2010). In particular, SMEs typically possess passive reactions towards CSR and sustainability partly due to insufficient financial resources and competencies as well as informal management systems compared with large corporations. This puts them in a weak position when implementing CSR-related organisational practice (McWilliams & Siegel, 2001; Jenkins, 2004; Park & Ghauri, 2015). Typically, the informal nature of SME management systems is often seen as a hindering factor to adopt and implement CSR practices (Baumann-Pauly et al., 2013). For SMEs, the commitment to CSR tends to be implicitly reflected in their internal structures and procedures with no formalised system to promote CSR practices and processes (Baumann-Pauly et al., 2013). In this vein, Baumann-Pauly et al. (2013) indicate that large organisations seem to be better equipped at organising and implementing CSR explicitly in their formal organisational practices and procedures which allow them to interact efficiently with stakeholders when compared to SMEs. In both cases, for SMEs and for large organisations, collaboration with external society is a key driver in promoting and implementing CSR practice (Baumann-Pauly et al., 2013; Reyes-Rodriguez et al., 2016; Winsor, 2006). Knowledge of these enabling and inhibiting aspects could provide CSR implementation practice in SMEs and under this premise, this research incorporates a comprehensive stakeholder- and institutional-based framework to understanding CSR in SMEs, to which we now turn.
The Dimensions of CSR from Stakeholder Theory and Institutional Theory

In principle, both stakeholder theory and institutional theory are interlinked and contribute to CSR on various levels which provides a guide to the drivers that initiate and motivate SMEs to adopt CSR as well as the enablers that facilitate SMEs in achieving CSR activities in their business practices. Accordingly, we can suggest possible avenues to illustrate the dimensions of CSR in supply chains and demonstrate the degree of implementation of these CSR practices from an SME perspective, integrating stakeholder theory and institutional theory. Stakeholder theory specifies the extent to which corporations interact with their stakeholders appropriately (Laczniak & Murphy, 2006). It also illustrates the dimensionality of CSR practices or thinking which can be used as a guiding tool in the implementation and evaluation of CSR into business operations (Mishra & Suar, 2010).

In the conceptualisation of CSR, the centrality of stakeholders has been emphasised by Campbell (2007). The primary stakeholders can include any individual, group, organisation, institution, community, and the environment (Spiller, 2000) as well as internal managers and employees, customers, investors, government, and suppliers (Panapanaan et al., 2003). They can even include any groups that may be required for long-term business survival and management (Mitchell et al., 1997). Over the last 20 years, some SSCM literature has discussed wide-ranging forms of stakeholders which affect pressures to adopt sustainable thinking, practices, or activities (Gonzalez-Benito & Gonzalez-Benito, 2006; Wolf, 2013).

More precisely, current research on CSR from a stakeholder perspective fails to include discussion of all or wider stakeholder mandates (Obersede et al., 2013). The omission of all or wider stakeholders is partly due to a poor and different conceptualisation of CSR in the literature and practice which affects directly or indirectly the identification of accurate boundaries for whom corporations are responsible (Donaldson & Preston, 1995; Jones, 1995). The tensions between business-driven and stakeholder-driven systems and issues of CSR are closely inter-related. Within the stakeholder perspective, there are various ways in which stakeholders determine significant parts in supply chains as facilitators as well as hinderers. Thus, SMEs are required to take in all stakeholders ‘who can affect, or are affected by, the achievement of an organization’s mission’ (Freeman, 1984, p. 54). Consequently, developing CSR for SMEs is complex and involves strategic decisions to formulate how they encounter CSR activities or sustainability goals into their operations at a corporate level (Polonsky & Jevons, 2009; Schneider & Wallenburg, 2012). More importantly, Baumann-Pauly and Scherer (2012) highlight the importance of interacting and engaging with relevant internal as well as external stakeholders, which can facilitate SMEs to adapt their internal organisational structures to ensure the embeddedness of CSR-related practices.

While the role of stakeholders has been widely researched, the role of institutions has been relatively ignored in CSR research (Brammer et al., 2012). Institutional theory determines companies are socially embedded within a set of formal institutions such as government regulations, and informal institutions such as norms, conventions, and shared beliefs (North, 1990). In this vein, it facilitates identification of the different boundaries between business associations and society. Within the dominant stands in institutional theory, there are two aspects of CSR: its diversity and its dynamics (Tempel & Walgenbach, 2007). Scott (1995) illustrates several social and cultural pressures that SMEs may face and be required to fulfil within their specific institutional environments and networks for social norms and rules. Given that the stakeholders’ demands are linked to institutional pressures (Yang & Rivers, 2009; Reimann et al., 2012), in complying with these institutional pressures, SMEs in supply chains may require adaptations of their values, processes, structures, and business practices. In the course of institutionalisation, CSR takes a wider boundary of the market and government regulations. Thus, an institutional theory views CSR practices beyond the territory of voluntary action.

This paper critically examines the contributions of stakeholder theory and institutional theory to understanding the CSR practices in SCM and to investigating CSR-SME relationships. Underpinned by these two theoretical foundations, this research conceptualises the key dimensions of organising and implementing CSR in practices specifically from an SME perspective.
Research Methodology

The aim of this paper was to conceptualise the dimensions of CSR in supply chains and to explore their relative importance and implementation from an SME perspective. Also, it sought to investigate the drivers of CSR implementation based on institutional theory and stakeholder theory. The empirical data for this study are from a large-scale questionnaire survey with South Korean SMEs in manufacturing sectors and panel discussions, to which we turn next.

Survey Data Collection

To investigate CSR in supply chains, a large-scale questionnaire survey was conducted with SMEs in South Korea. The survey sample was constrained to manufacturing firms that are directly or indirectly involved in global supply chains so that supply chain contexts could be fully integrated into the survey responses. South Korea is a rapidly developing economy which has recently increased awareness of CSR issues in its global SCM. For this research, Gyeongbuk province in South Korea was selected for its long tradition of strong focus on manufacturing sectors. A total of 200 questionnaires were distributed via e-mail to SMEs based in the province from February to March 2015. The list of these SMEs for this survey was obtained from a government organisation, Gyeongbuk Pride Product Support Centre, which has supported the internationalisation and marketing of SMEs in the region since 2009. The South Korean government defines an SME as a firm which employs fewer than 300 employees in the manufacturing sector.

The questionnaire consists of four parts. Following the first part which asked general information about participating firms and respondents, the second part was designed to measure the relative priority of CSR dimensions and CSR practices by pair-wise comparisons. In the third part, respondents were asked to assess the implementation level of CSR practices in their organisations. The last part covered the evaluation of contingencies that may affect the level of CSR implementation based on institutional theory and stakeholder theory, namely regulatory impact, normative impact, cognitive impact (institutional theory) and customers, government, suppliers, competitors, local community, and non-governmental organisations (NGOs) (stakeholder theory). The third and fourth parts were measured by 7-point scales. Before commencing the large-scale survey, this questionnaire was reviewed by CSR experts and then by a pilot study to examine the applicability and validity of measurement items. A total of 87 questionnaires were collected from top and middle managers, showing the response rate of 43.5% which is a relatively moderate response rate compared to that of other SCM research. In CSR research, this response rate may be lower than some previous surveys (Strachan, 1999; Sangle, 2010), but is still higher than other surveys (Holt 2004; Beske et al., 2008). We acknowledge the limited sample size of this research. No missing data and non-response biases were detected; thus, all responses were used for the analysis. The profile of respondents is shown in Table 1.

Data Analysis

Research Procedure

For this paper, step-wise analysis using analytic hierarchy process, importance-performance matrix, and ANOVA were used. In the following sections, we outline six step-wise processes of the research procedure in detail.

Step 1 - Define CSR Dimensions in Supply Chains
Step 1 generates a vital theoretical framework to comprehensively understand the dimensions of CSR applicable both to corporate level and supply chain levels. In particular, it focused on the social responsibility of supply chains and its operational definitions. A thorough review of extant CSR-SCM literature was conducted to construct the framework of multi-faceted CSR dimensions which are holistic yet parsimonious. This framework was reviewed by a panel discussion of five industry experts in CSR and modified according to their feedback to ensure its validity. Based on the framework, a survey questionnaire was designed to capture (i) pairwise comparisons between CSR dimensions, (ii) the implementation level of each dimension and (iii) the impacts of institutional factors and stakeholders on CSR.

Step 2 – Evaluate the Relative Importance of CSR Dimensions
Step 2 aims to understand which dimension is perceived the most important in SMEs’ CSR in a supply chain context. In particular, the importance of a supply chain social responsibility dimension can be numerically evaluated in a comparison of established CSR dimensions. Analytic hierarchy process (AHP) is a technique for multiple criteria decision making (Saaty, 1977) which can produce the relative importance of each criterion by pairwise comparisons between criteria. The application of AHP in this research provided specific priorities among CSR dimensions. In the large-scale questionnaire survey, the respondents were asked the pairwise comparisons between three main CSR dimensions (corporate environment dimension, corporate social dimension, and ethical supply chain dimension) and between sub-dimensions of each CSR dimension. On a 9-point scale to each end, the respondents evaluated the extent to which they think one dimension is more important than the other. The results were converted into \( \frac{1}{9} \) to 9 scales as suggested by Saaty (1980), and individual responses summarised as a representative perception using geometric means.

Step 3 – Demonstrate the Average Implementation Level of CSR Dimensions
At Step 3, the implementation level of CSR dimensions is captured by the mean of 7-point-scale measurement from the large-scale questionnaire survey.

Step 4 – Analyse the Importance and Performance by a 2X2 Matrix
With the results from Step 2 (relative importance) and Step 3 (performance), a performance-importance matrix can be generated with mean-centred values. ‘Relative’ importance was used for this matrix which is the main difference from the normal performance-importance matrix. Further discussion was made from this matrix to evaluate the CSR practice of SMEs in supply chains.

Step 5 – Generate three Groups by Overall Weighted Index
With AHP results being used as a weight of each dimension of CSR in supply chains, the Overall Weight Index (OWI) of CSR implementation of respondent firms can be derived (Jharkharia & Shankar, 2007). The OWI can be calculated by the following formulae:

\[
\text{OWI} = \sum_i (\text{Weight}^i \times \text{Performance}^i)
\]

where \( i \) = a sub-dimension of CSR.

Based on the OWI, respondents were grouped into upper, medium, and lower groups in terms of CSR implementation.
Step 6 – Validate the Impacts of Various Drivers on CSR Practices
The impacts of various drivers on CSR practices from institutional theory and stakeholder theory can be validated by comparing the perception of these drivers between the upper and lower groups. If the drivers are effective, the mean values of the upper group should be significantly higher than those of the lower group. If there exists a statistically significant mean difference in driver A, its impact on CSR implementation can be confirmed. ANOVA, a statistical tool to test as to whether the mean of two or more groups is equal or not, was used and the statistical significance tested with the 5% significance level.

Results

Following step-wise research process, the results are presented in five sections: dimensions of CSR in supply chains, relative importance of CSR dimensions, the level of CSR implementation, performance-importance matrix of CSR dimensions, and the impacts of CSR drivers.

1. Dimensions of CSR in Supply Chains
In general, CSR consists of an environmental dimension and a social dimension. But most CSR literature focuses on the social dimension, dividing it into several sub-dimensions, such as labour, health and safety, human rights, community, society, etc. The environmental dimension, on the contrary, tends to be captured by just one dimension, although green logistics and/or SSCM literature describes this dimension in detail, including but not limited to material handling, waste management, and packaging and transport (Zhu et al., 2008; Rodrigue et al., 2009). Moreover, since the current CSR dimensions are developed from an individual firm’s perspective, it is

Table 2. Dimensions of CSR in supply chains
challenging to capture the CSR dimension applicable to the supply chain level. Therefore, it is a pre-requisite to find appropriate CSR dimensions in supply chains.

For this purpose, a review of existing literature on CSR, green logistics, and SCM was conducted. In particular, Global Reporting Initiative (GRI) (2013) Sustainability Reporting Guidelines (GRI-G4) was useful because it suggests comprehensive criteria to be applied to a firm’s CSR. At the supply chain level, only a few SCM research focused on how to implement CSR across the supply chain, and suggested supplier assessment, ethical collaboration (Gimenez & Tachizawa, 2012), awareness building and training (Ciliberti et al., 2008), and evolution of governance (Alvarez et al., 2010). In particular, Carbone et al. (2012) explicitly distinguished CSR from supply chain social responsibility by considering measurement items for both environmental and social aspects of supply chains.

One critical difference of this research is the creation of an ‘ethical supply chain’ dimension to address CSR issues in supply chains. The extant studies on CSR-focused social and environmental dimensions are in line with GRI-G4 and applicable to the report of ‘a company’. However, when supply chains with various entities are considered, it is necessary to have another viewpoint which can incorporate the social responsibilities from suppliers to end customers. In this circumstance, this research has used the same practices and indicators discussed by literature and GRI-G4, but aligned them with corporate environment, social, as well as ethical supply chain dimensions.

A set of CSR dimensions and their practices were identified based on GRI-G4 and extant research, and then reviewed by five CSR experts. They discussed CSR dimensions and practices for a parsimonious model, which led to a debate as to whether the supply chain dimension should take the same hierarchy as the environmental and social dimensions. Some of them suggested four dimensions, taking the model of Carbone et al. (2012) which consists of corporate-social, corporate-environmental, supply chain-social, and supply chain-environmental dimensions, into account. Eventually they agreed that at least one supply chain dimension would be needed to capture the unique contributions of SSCM to CSR. As a result, the framework of CSR dimensions in supply chains can be drawn as seen in Table 2.

### 2. Relative Importance of CSR Dimensions

Based on the CSR consolidated dimensions, the relative importance of each dimension and its practices were calculated by AHP. Four analysis were conducted using the SuperDecisions software package to identify the relative weights among three CSR dimensions and among practices within a dimension. All the analysis showed the consistency indices less than the threshold value of 0.1, which means the responses were logically consistent. The results are demonstrated in Table 3 in a descending order of relative weights. Two established dimensions, Corporate Society and Corporate Environment, accounted for 80% of the importance with similar levels of weights between the two. The Ethical Supply Chain dimension, on the other hand, was perceived less important than the other two. However, it also accounted for 20% of the total importance, showing the potential to be an independent dimension that can effectively illustrate CSR in supply chains.

*Table 3.* The weights of CSR dimensions
At the practice level, health and safety was highly prioritised by SMEs (20.64% out of 100%). This is attributed to the fact that SMEs have fewer employees who are exposed to dangerous working conditions. Other two social practices, local community and labour, have drawn the attention of SMEs to significant extents (11.72% and 11.48%). Two environmental practices, environment products (15.00%) and environmental sites (11.72%), were ranked highly whilst material management was perceived as relatively low. Three practices in the ethical supply chain dimension placed at the bottom, which is mainly because the dimension itself was less important than other two established dimensions. The relative weights of CSR practices will be further discussed in Step 4 along with their performance levels.

3. The Level of CSR Implementation

The level of CSR implementation was measured by the mean. The results show that consumer protection (5.3 out of 7) is the most implemented practice, followed by environmental products (5.01) and environmental sites (4.86). While local community (4.6), supplier assessment (4.6), health and safety (4.53) and ethical collaboration (4.52) are located in the middle of the table, labour (4.47) and material management (4.37) were selected as the least implemented practices. This finding is in line with empirical findings of Achabou et al. (2015) and Carbone et al. (2012), which showed the implementation of customer-related as well as environment-related practices was higher than that of society-related practices.

4. Performance-Importance Matrix of CSR Dimensions

To analyse the implementation level in combination with the relative importance of each CSR sub-dimension, a 2 × 2 matrix was generated as shown in Figure 1. All values were modified to be mean-centred. Among the CSR practices, environmental products and sites were well recognised by SMEs, and at the same time, were embedded in their CSR practices. Consumer protection, on the other hand, was heavily implemented in the practice, but its importance was relatively low. These practices are commonly explicit to customers, which can easily build up a relatively good social reputation.

Figure 1 illustrates the importance of practices in the corporate social dimension which was highly regarded but the implementation level was less than expected. In particular, health and safety was not appropriately addressed by SMEs, despite its highest importance. This can be explained by cost issues because these practices will require immediate spending which cannot be easily implemented by SMEs given their financial constraints. If SMEs seek their competitiveness from cost advantages, emphasis on practices for society can be just rhetoric. On the contrary, two major environmental practices, including environmental products and environmental sites, were rated highly.

Figure 1. Performance-importance matrix of CSR dimensions. [Colour figure can be viewed at wileyonelibrary.com]
both in terms of importance and performance. This result reflects the fact that environmental aspects have been regarded as established drivers of a firm’s competitive advantage by SMEs.

In terms of the operational aspects, they are often implicit to customers which were not highly considered by SMEs. These include supplier assessment, ethical collaboration, and material management, which commonly require a certain level of strategic decisions to implement in the operations. In particular, these operational practices are one of the prolific research agendas in SCM disciplines which have suggested many innovative ideas, but SMEs tend to be less focused on these practices. This can be explained by power relations in the supply chain. With less power in the supply chain, SMEs may be limited to prioritise and initiate supplier assessment, ethical collaboration, and material management. With regard to the material management practice, SMEs have to use enough energy and best materials, regardless of their environmental impacts, to meet the requirements of powerful customers.

5. The Impacts of CSR Drivers

Given the relative weights of CSR practices and the performance of participating companies, the overall CSR level of each SME can be calculated. The highest and lowest CSR levels were 5.8 and 3.15 out of 7, which indicated that there are clear discrepancies in CSR implementation across the SMEs. Also, it means that there should be some contingencies which create this difference. This research thus further tested the impacts of contingencies from stakeholder theory and institutional theory on the SMEs’ CSR level by comparing the means of the better group and the worse group. From stakeholder theory, we identified six factors (customers, government, suppliers, competitors, NGOs, and local community). Three factors (regulatory, normative, and cognitive pressures) were drawn from institutional theory, as shown in Table 4.

The ANOVA results showed that there are significant differences in CSR implementation level given all these contingencies. This implies that the theories are effective even in the SME and supply chain contexts. When the overall mean values are considered, drivers of customers and government from stakeholder theory, and regulatory pressures from institutional theory showed the highest mean values. This finding is in line with other studies which have explored the relationships between stakeholder/institutional pressures and CSR implementations (Kim et al., 2013; Meixell & Luoma, 2015). Park and Ghauri (2015) found that consumer, competitors, and NGOs are the primary determinants of CSR practices of SMEs, but this study showed that all stakeholder pressures can generate significant changes in the practice. Interestingly, when the overall mean values are considered, customers and government from the stakeholder theory showed the highest mean values, which is quite consistent with Park and Ghauri (2015). When it comes to institutional theory, regulatory pressures showed the highest mean values compared to those of normative and cognitive pressures. This finding can demonstrate that if SMEs are under the scrutiny of various stakeholders or regulations, their participation in CSR practices will be generally high (Udayasankar, 2008).

Conclusions and Implications

CSR has become a centre of attention for scholars and practitioners because of its well-recognised importance to developing sustainable practices. This research explores the dimensions of CSR in SME supply chains, and examined how SMEs consider CSR practices by analysing their importance and performance. It provides an essential insight specifically in the context of South Korea. Based on stakeholder theory and institutional theory, this research also investigated the impacts of various contingencies on the level of CSR implementation. Given the complexity of the CSR implementation process, it can be concluded that SMEs tend to focus on explicit CSR practices that can be easily identified by their customers. On the contrary, operational issues hidden to their customers are not considered in SMEs’ CSR practices. Characteristics of SMEs such as resource constraints, imbalanced power within their relationships with customers, deficiencies in CSR strategies, and lack of supply chain innovation may explain this trait in SMEs’ CSR.

From this discussion, ANOVA analysis empirically shows that stakeholder and institutional pressures are valid in the performance of CSR practices for SMEs. However, the level of pressures was largely biased to external pressures (Darnall et al., 2008) such as customers, government, and regulatory pressures, which means that SMEs tend to be more reactive rather than proactive when it comes to implementing CSR practices. This can imply that SMEs recognise CSR issues as risk sources that generate stakeholder reaction and in turn lead to damage to their firms (Hofmann et al., 2014). In this regard, this research has its value in investigating CSR practices within supply chains specifically taking the SME perspective, which has not been fully explored in the SCM discipline on its own merits.

Interpreting our findings of this study yields several theoretical, practical, and policy implications. The study empirically analysed the practices and contingencies of CSR implementation using survey data and various statistical techniques including AHP, importance-performance matrix, and ANOVA, which effectively demonstrated the strong and weak areas of SMEs’ CSR activities. It is applicable to other industry sectors for comparative analysis but individual environments will differ significantly. The impacts of contributing factors from institutional theory and stakeholder theory have been validated even in the SME context. These theoretical values can be also applicable to managerial implications. The CSR dimensions and practices can be used as a check list for firms to achieve balanced CSR implementation. In addition, to evaluate the degree of CSR implementation, our theoretical framework can be used as an index to compare the CSR level of SMEs.

In highlighting the dimensions of CSR in the SME context, this study holds implications for public policy. SMEs make up over 90% of the global population of corporations which therefore have significant contributions in social and economic-related activities (Udayasankar, 2008; Jamali et al., 2009; Naem & Welford, 2009). Given their importance, governments should develop specific policies on CSR for SMEs as typically SMEs have intrinsic differences when compared with large organisations which come in the form of legal structure, policies, strategic orientation towards profit, and institutional forms (Perrini, 2006).

Since SMEs typically display passive reactions towards CSR because of their financial constraint and limited systems, which often place SMEs in a weak position when it comes to implementing CSR practices, governments should raise CSR awareness and practices through soft policies on SMEs and offer consultation more widely. Government organisations could also introduce incentive systems or partial financial assistance to SMEs in support of CSR practices (McWilliams & Siegel, 2001). In this way, SMEs’ commitment to CSR could be better and more explicitly reflected in their internal structures and procedures, which would allow them to also engage with stakeholders (Baumann-Pauly et al., 2013). Collaboration with external society including stakeholder engagement is an important dimension in motivating and implementing CSR practices (Winsor, 2006).

Even though our research is based on CSR in SME supply chains, we believe that our discussions and findings are instructive for considering the development of larger organisational CSR capabilities taken as a whole. Therefore, this paper is of high relevance to practitioners and policymakers looking to implement and manage CSR practices for organisations. Overall, this study establishes a basis for companies developing CSR practices in developing economies by highlighting consolidated dimensions in CSR supply chains in manufacturing SMEs in South Korea.
Limitations and Future Research

As with all research, this too has several limitations which offers indications of the potential avenues for future research. Conducting the survey with SMEs in a single, developing-country context in the manufacturing sectors with a focus on SMEs, limits the degree of likely generalisability of the findings of this research. Further research could explore a comparative analysis with larger firms in other environmental contexts, such as service industries, which may highlight the distinctive features of SMEs’ CSR practices in supply chains for replications. In this paper, we collected a total of 87 out of 200 questionnaires and the relatively low response rate (43.5%) might be because CSR could be a sensitive issue for some of manufacturing SMEs in South Korea. The relatively small sample size of firms limits the generalisability. Another limitation is related to the self-perception issues when conceptualising the CSR dimensions as well as interpretations of our findings; some caution is required when interpreting our empirical results.

Other limitations include the single response, cross-sectional nature of this research which may not offer an overall picture of the dimensions of the CSR implementation process over time. Further research could employ a longitudinal approach to offer a fuller understanding of CSR implementation to extend or confirm our results. Building on these limitations, further research could replicate the research methodology to other developing countries and industries and it could be complemented with qualitative research which may strengthen our findings. This study, however, provides insights into understanding SMEs’ CSR at a fundamental level.

Acknowledgments
